Abstract

The GPS signal is vulnerable to both intentional and unintentional interferences due to its low received power. The need to localise GPS interference sources is becoming more pressing as more systems rely on GPS, while GPS jammers are becoming more widely available. This thesis discusses techniques to estimate the direction of arrival (DOA) of weak interferences in the GPS frequency band using antenna arrays.

The main issues which affect weak GPS interference DOA estimation accuracy are the antenna array errors, interference from other GPS signals, the number of snapshots required for DOA estimation and system coloured noise.

In order to estimate antenna array errors, a modelled eigenstructure based antenna array calibration algorithm is presented. This algorithm describes the antenna array errors using a physical model and uses the GPS signals with known DOAs as disjoint calibration sources to reduce the number of unknown calibration parameters and to enable a larger number of possible calibration sources to be used.

GPS calibration sources often have multipath components. These multipath components will contaminate the mutual coupling estimation result due to a similar directional behaviour. In order to solve this issue, a new calibration algorithm is developed to estimate the mutual coupling matrix in the presence of multipath signals. This algorithm first uses the decomposed signal subspace to construct its calibration cost function and then estimates the calibration parameters using alternating projection based methods iteratively.

The GPS signals typically have a SNR range from -15dB to -30dB. If the INR of the weak GPS interference is close or lower than this range, GPS signals need to be mitigated as they act like strong interferences. A Multiple

Subspace Projection (MSP) algorithm is proposed to cancel GPS signals. This algorithm projects the received signal onto the orthogonal subspace of GPS signals to cancel them completely even if the signals are band-limited, have multipath components, or have fractional delays.

The number of snapshots in the received data significantly influences the DOA estimation variance. The Cramer-Rao Lower Bound (CRLB) is derived and analysed for the antenna array DOA estimation. By using the CRLB, the number of snapshots is required to be larger than 1×10^6 to have the DOA estimation standard deviation to be smaller than 0.25° for a signal with a SNR of -20dB.

Finally, after cancelling GPS signals using the MSP algorithm, whitening the coloured noise in the system by using noise only data and calibrating the antenna array, the experimental results using an eight-element GPS antenna array showed that the DOA of a weak GPS interference with a SNR of -22dB could be accurately estimated.

Declaration

I certify that this work contains no material which has been accepted for the award of any other degree or diploma in my name, in any university or other tertiary institution and, to the best of my knowledge and belief, contains no material previously published or written by another person, except where due reference has been made in the text. In addition, I certify that no part of this work will, in the future, be used in a submission in my name, for any other degree or diploma in any university or other tertiary institution without the prior approval of the University of Adelaide and where applicable, any partner institution responsible for the joint-award of this degree.

I give consent to this copy of my thesis when deposited in the University Library, being made available for loan and photocopying, subject to the provisions of the Copyright Act 1968.

I also give permission for the digital version of my thesis to be made available on the web, via the University's digital research repository, the Library Search and also through web search engines, unless permission has been granted by the University to restrict access for a period of time.

Acknowledgements

I would like to thank Professor Douglas Gray, my principal supervisor, for supervising and supporting this thesis. He introduced me to the field of array processing and gave me freedom to explore new ideas.

I wish to thank my supervisor Mr. Matthew Trinkle for his patience, guidance and assistance during my Ph.D. study, and providing me with extremely useful analysis, discussions and suggestions on my research.

I also would like to thank my friends and colleagues at the University of Adelaide Radar Research Centre and Sensor and Signal Processing Group at the University of Adelaide, in particular Ruiting Yang, Chow Yii Pui, Federica Salvetti, Tishampati Dhar, Rowen Fry, Joy Li, Mr. Marian Viola and Dr. Danny Gibbins.

Finally, thanks to my parents and my daughter, for all the love and strength they give me. And thanks to my wife Xiuran Zhu, without her support and encouragement, I would never have had the energy to see this thesis through to completion.
