ABSTRACT

The ability to stimulate a fertile oestrus during lactation provides an opportunity to increase piglet weaning age whilst maintaining 2.4 litters per sow per year. Determining the optimal time and method to induce lactation oestrus in the sow as well as ensuring subsequent reproductive outcomes are not negatively affected are vital for the commercial adoption of lactation oestrus systems. Research reported in this thesis investigated firstly, the stimulation of a fertile oestrus early in the post partum period, and secondly, the effect of boar contact and split-weaning in late lactation on oocyte quality, early embryo development and embryonic gene expression. Experiment one demonstrated that the provision of full daily boar contact from day 7 post parturition resulted in a significantly higher proportion of sows expressing lactation oestrus within 26 days of farrowing compared to sows that received no boar contact. Of sows mated within 26 days of farrowing, there was no effect of boar contact or weaning at 7 days on number of piglets born in the subsequent litter. Experiment 2 followed on from a previous study which demonstrated improvements in subsequent litter size when sows had a portion of their litter weaned (split-weaned) prior to mating in lactation. We demonstrated that reducing litter size from 11 to 7 piglets on day 18 of lactation did not increase in the percentage of ova fertilised *in vitro* or the percentage of ova that developed to blastocyst stage from sows slaughtered on day 21 post parturition. Follicular fluid concentrations of oestradiol were higher in split-weaned sows; however, the capacity of the collected follicular fluid to support *in vitro* maturation of pre-pubertal oocytes was unaffected by suckled litter size. Blastocyst development rates were lower for sows which lost > 5% compared to < 5 % of their body weight from day one to 21 post parturition. Sows split-weaned on day 18 post parturition, mated in lactation and slaughtered on day 30 of gestation had higher embryo survival compared to sows split-weaned at oestrus or suckling a full litter

for the duration of lactation. Split-weaning either on day 18 of lactation or at the first detection of lactation oestrus resulted in higher pregnancy rates and heavier embryos compared to sows suckling a full litter of piglets. Split-weaning resulted in minimal differences in gene expression of day six *in vitro* produced embryos or day 30 *in vivo* produced embryos. Overall, this thesis demonstrates that boar contact is an effective stimulant of lactation oestrus in multiparous sows and reducing the litter size prior to mating in lactation and minimising sow weight loss over lactation is beneficial to the subsequent litter.

ACKNOWLEDGEMENTS

The decision to undertake this PhD was quite an easy one and I have honestly enjoyed every moment. There are many people that have helped me along this process and made the last five years such a great experience. Thank you firstly to my wonderful supervisors; to Will who took me on as an honours student and introduced me to the world of pigs, reproduction and research. I've learned so much from him in the last six years and I thank him for all his help and guidance. To Karen, her knowledge is incredible, her door was always open and I thank her for often being the voice of reason. And to Roy, for his extra set of ears to bounce ideas off.

Thank you to the Pork CRC, in particular Roger Campbell, for the amazing opportunities I had as a Pork CRC funded student to present at international conferences and spend three months at the University of Alberta learning microarray techniques.

Thank you also to Paul (Harry) Herde for all the help he gave me at the piggery, all done with a smile and a laugh. To Jen Kelly, I am so grateful to her for welcoming me into her lab and teaching me IVP. Also thank you to the rest of the team at Turretfield Research Centre, Dave, Skye, Ian, Caroline, Anthony, Kaylene and Jack.

I'd like to thank Kate and Paul and the Roseworthy Pig Group, the staff at the Roseworthy Piggery and the Roseworthy community in general. Thanks also to George, Mike, Stephen, Joan, Tracy and the students from the University of Alberta.

Special thanks must go to Robyn and Michael, my fellow PhD students and good friends. The last five years were made much easier having these two with me.

Finally, the support from my family and friends has been amazing throughout my PhD. To Caitlin, Jess, Tahlia and Lauren. To Mum, Dad, Sarah and Sophie, we are a tight knit family and I cannot thank them enough for all the support and the help they gave me when I often roped them into helping with experiments.
